Collinearity in the gene order between two chromosomes is generally considered one of the hallmarks of the taxonomic higher-order classification of prokaryotes. However, it has been argued that the existence of collinearity, or its absence, might have little to no impact on the classification of prokaryotes, because it is not easily detectable by standard phylogenetic methods. In this study, we show that the general assumption that collinearity is a standard criterion of bacterial classification is unfounded. The difficulty in detecting it in traditional phylogenetic analysis is due to the fact that only one gene order (i.e., a prokaryotic genome sequence) is provided for each of the two taxonomic branches of a tree. On the contrary, the "shadow" of collinearity can be detected by a straightforward recursive algorithm in the presence of more than two orders of genes. Our results are demonstrated using an example of two bacteriocin gene clusters located on two homologous linear plasmids.
